AEL Product Requirements

1 Problem and users

Our research team works with Dutch sources about AI in sportswear and retail. Not every team member speaks Dutch, and preparing an English handbook takes time. Our tool helps with translation, organising evidence, creating a PDF and uploading it to GitHub.

The main users are students in our research team. The intended reader is a non-technical SME manager, but the handbook needs human review before it is used as advice. This version describes the prototype delivered on 25 October 2026.

2 What the user must be able to do

- Add a public Dutch text file or paste Dutch text into the terminal.
- Translate it into clear English, with a target reading level of B1/B2, while keeping its source details.
- Save the translation and inspect the Dutch and English texts in a local wiki archive.
- Select saved translations and create a handbook with references and clear sections.
- Review the handbook and choose whether to upload its PDF to GitHub.

3 Output requirements

The handbook should clearly separate information from the sources from our suggested next steps. It should show where its evidence came from and should not invent a company case, budget, percentage saving or return on investment.

The output language is English. This replaces the conflicting Dutch-output requirement in the previous PRD. Some source titles and dates remain in their original language. Our demonstrated input files are short AI summaries, not full articles. The local wiki stores translations; it does not automatically contain the handbook PDF.

4 How we judge the result

Requirement	Current result
Translation	Three short sources were processed in the demo. The longer CBS article failed a numeric check. Meaning errors are still possible.
Clear language	The model aims for B1/B2 English. There is no separate numeric readability score.
Traceable evidence	The handbook has source labels, supporting English passages and a bibliography. This does not verify the original websites.
Visible outputs	The demo shows the generated PDF on GitHub and the source records in the local wiki.
Human control	The user chooses which translations to use and whether to publish. The program cannot prove that the user reviewed the result.

5 Constraints and recovery

The tool needs a local setup and is used through the terminal. It does not automatically fetch URLs, process interview audio or assess private company data. The archive stores input before anonymisation, so we only use public, screened material.

If a translation fails, we investigate the error or leave that source out. We do not bypass the checks. If only the upload fails, we keep the handbook and retry after fixing GitHub access. A saved translation must remain with its matching metadata file.

6 What we did not complete

The earlier PRD proposed automatic source-quality scoring, detailed teamwear use cases, three AI maturity tiers and measured ROI. It also proposed Flesch-Kincaid scoring, a one-page Quick-Start Action Sheet, a fixed rule for visual spacing and a pilot that could start within 48 hours. These are not delivered or verified features.

Automatic GitHub Pages publication, full dependency version pinning and reliable performance on every laptop are also not established. Our final handbook is a short evidence-based overview, not a complete company-specific implementation plan.

7 Next improvements

We should improve difficult translations, check our summaries against the full original sources and make quality reports easier to understand. We should also test the setup on another computer. More detailed operational advice needs stronger sources and separate research before we can claim business benefits.
