AEL Build Plan

1 What we built

We built a tool that helps our team work with Dutch sources about AI in sportswear and retail. It translates the texts into English, creates a handbook and can upload the handbook PDF to GitHub. It also saves the Dutch input and English translation in a local wiki archive.

This version describes our final prototype on 25 October 2026. Some ideas from our earlier plan were not completed. We list these as future work instead of presenting them as finished features.

2 Main steps

Step	What we did
Prepare the sources	We selected public sources and added Dutch text files. Our demo uses short summaries of Nike, SBB and NHL Stenden pages.
Translate the text	The tool checks for personal details, translates the text, simplifies the English and reviews the result.
Check and save	The tool checks the translation against the Dutch input. It saves an English TXT and a matching source metadata file.
Create the handbook	We choose the saved translations. The tool checks them and creates a handbook with source references.
Publish and show the archive	We choose whether to upload the PDF to GitHub. We can also open the local wiki to compare the input and translation.

3 Team responsibilities

Product manager chooses and checks sources. The developer maintains the tool. The tester checks its results and the deployer checks that it is available on GitHub. These are roles in the workflow.

4 What we tested

We tested whether the translation really fits the B1/B2 level and if all personal data is properly anonymized. In our demo, we processed three articles to generate the final handbook, and the video shows the new PDF pushed to GitHub and saved in our local wiki.

Not everything passed on the first try: a longer CBS article failed our check because some numbers got mixed up during translation, so we left it out of the demo.

5 When we accept a result

- A translation must pass the tool's checks before it is accepted. The tool tries one repair if needed and stops if the problem remains.
- A saved translation must stay together with its .source.json file. The handbook needs both files to check that they belong together.
- We review the handbook before choosing to publish. The program asks for confirmation, but it cannot prove that somebody has read it.
- We check the exact new PDF on GitHub. The publisher uploads only that PDF, not all local project files. It does not create a pull request.

6 What remains to improve

We need better support for long texts with numbers, more reliable translations and clearer quality reports. Automatic source-quality scoring, measured readability scores and detailed company-specific advice are not implemented.

If only the upload fails, we keep the existing handbook and retry publication after fixing access. We do not need to translate everything again. A manual document is still possible, but we must not describe it as a result that passed the automated checks.
